

Flounder processing line

ZATOKATECH
Optymalizacja procesów

System description

The initial element of the line is the washer-feeder, which transfers the flounder to the inspection sorter belt. The fish product is distributed here in terms of volume, length, weight or type (depending on the user's settings). The undesirable elements are at this stage transferred to the waste container. After the sorting process, the flounder is sent to the filleting devices. Received waste is transferred to offal systems, and finished fillets are conveyed to the scale, and then to the containers or transport trays (depending on the user's requirements).

Flounder processing line is a very precise and economical system that allows you to receive a finished product with minimal employee involvement.
